

When parsing my example sentence, I have come with the opinion that PSG parsing/constituency parsing does the best job at clearing up the syntactic ambiguity that occurs in language, at the cost of not providing as much information on how individual parts of speech relate to each other. This is the opposite of dependency parsing, although in my opinion it was by far the most difficult to perform on the sentence. Finally, SRL parsing is a bit of a mix of the two. It provides a good amount of information on the roles of the constituents that are related to the predicate(s), but I believe it could use some more modifiers to have a greater amount of information to add.
